Kotiutusohjeet: Tosca

Clinical Report: Tosca

Tosca gave birth approximately 10 months ago. She typically has clearly timed heat cycles twice a year. Based on this regular pattern, the owner expected Tosca to come into heat at the beginning of this month. However, to date, she has not shown any obvious signs of estrus.

Since a suitable male is waiting for her in Norway, we aimed today to determine her current stage in the reproductive cycle.

General Examination:

No clinically significant abnormalities were noted. Upon closer inspection of Tosca's oral cavity, we observed:

- A mild underbite and an open bite.
- A slightly narrow lower jaw (micrognathia), resulting in limited space for the lower incisors and subsequent misalignment.
- A minor shift of the dental midline (the gap between teeth 101 and 201) to the right. Despite this, the jawbone itself appears symmetrical and centered.

Reproductive Assessment:

Vulvar examination:

- Slight vulvar swelling with mild bloody discharge noted.

Vaginal inspection:

- Mild swelling of the vaginal walls
- Pink mucous membranes
- Mild bloody discharge

Vaginal cytology findings:

- Mild presence of bacteria
- Few red blood cells
- No white blood cells

- Predominantly intermediate vaginal epithelial cells with a low degree of cornification

Progesterone testing:

- A blood sample was collected for progesterone analysis
- Result: Baseline level at 1.1 nmol/L

Summary:

- Tosca's heat cycle has begun.
- She is currently in early pro-oestrus.
- Ovulation timing cannot yet be predicted with certainty. However, based on her historically regular cycles, ovulation and the optimal breeding window can likely be expected in approximately 10 days (end of next week/weekend).

Follow-Up Plan:

- As the owner can travel to Norway within a day, we recommend starting progesterone testing early next week, followed by testing every second day until ovulation is approaching.
